

Completing the published record: a thread of evidence

Daniel Shanahan, Associate Publisher BioMed Central
EQUATOR/REWARD Conference, 28 September 2015

A 'crisis' in reproducibility?

- The current over-emphasis on results has led to many problems in the literature:
 - Publication bias
 - Selective reporting of outcomes and analyses
 - HARKing (Hypothesising After the Results and Known)
 - Significance chasing and low statistical power
 - Lack of data sharing and replication

Adequacy of Published Oncology Randomized Controlled Trials to Provide Therapeutic Details Needed for Clinical Application

Methods in the madness

- Research only has value if:
 - the hypothesis is relevant
 - the methods are valid
 - the findings are published in a usable form ←  This is where
we come in
- The value in science is in the QUESTION it asks and the PROCESSES it uses, not in the OUTCOME observed
- Traditionally, journals offer a précised version of the methods used; this meant that authors often simply cited a previous paper where this technique was used
- Instead we need full, detailed reports of the methods and these need to be evaluated and published **prospectively** to prevent publication bias, selective reporting, HARKing etc.

Prospective study registration

Registration is becoming increasingly commonplace, with evidence it helps to reduce publication bias*

*Emdin *et al. JAMA Intern Med.* 2015;175(2):304-307.

Evaluating research based on the methods...

This is not new:

- *Trials*, the *BMC series* and others have been calling for the prospective (before recruitment completes) publication of study protocols for almost 15 years
- More recently we have also begun publishing statistical analyses plans
- *Systematic Reviews* calls for the publication of systematic review protocols
- In 2013, the journal *Cortex* launched Registered Reports in clinical psychology
- We even have detailed, expert reporting guidelines for such protocols, which set out the minimum amount of information required to be reported:

...regardless of outcome or significance of findings

- The idea that ‘negative’, non-confirmatory results are valuable and should be published is gaining increasing support:

**JOURNAL OF NEGATIVE
RESULTS IN BIOMEDICINE**

World Health Organization

**BILL & MELINDA
GATES foundation**

- ‘Low impact’ publications, such as pilot and feasibility studies, are also increasing recognized as fundamental to research.

Effect of thrombolysis with alteplase within 6 h of acute ischaemic stroke on long-term outcomes (the third International Stroke Trial [IST-3]: a randomised controlled trial

The IST-3 collaborative group*

Summary

Background Few data are available from randomised trials of functional outcome in patients who have had acute ischaemic stroke. A secondary objective of the third International Stroke Trial (IST-3) was to assess the effect of alteplase on such outcomes at 18 months.

Methods In this open-label, international, multicentre, randomised controlled trial, 3035 patients were randomly allocated within 6 h of acute ischaemic stroke to alteplase (0.9 mg/kg; n=1515) plus standard care or standard care alone (n=1520). The primary outcome was the adjusted odds ratio (OR) for functional outcome at 18 months, defined as a modified Rankin Scale (mRS) score of 0-2. Secondary outcomes included mortality, quality of life, and the effect of alteplase on other mRS scores.

Findings At 18 months, the adjusted OR for functional outcome was 1.02 (95% CI 0.95-1.09) in patients who had received alteplase compared with those who had received standard care alone. There was no significant difference in mortality or quality of life.

Abstract

Background and Purpose—In acute ischemic stroke, the hyperdense artery sign (HAS) on noncontrast computed tomography (CT) is a surrogate for intraluminal thrombus and, therefore, is a surrogate for arterial obstruction. We sought to assess the accuracy of HAS for arterial obstruction in acute ischemic stroke.

Background and Purpose—In acute ischemic stroke, the hyperdense artery sign (HAS) on noncontrast computed tomography (CT) is a surrogate for intraluminal thrombus and, therefore, is a surrogate for arterial obstruction. We sought to assess the accuracy of HAS for arterial obstruction in acute ischemic stroke.

Methods We selected 15 cases from the Third International Stroke Trial (IST-3, ISRCTN25765518) with various degrees of arterial obstruction in different intracranial locations on CT. To assess inter-observer reliability, seven members of the IST-3 expert image reading panel (>5 years experience

Association between outcomes, and response to treatment in acute ischaemic stroke: data from the Third International Stroke Trial (IST-3): second randomised controlled trial

The IST-3 collaborative group*

Summary

Background Brain scans are essential to exclude haemorrhage in patients with suspected acute ischaemic stroke before treatment with alteplase. However, patients with early ischaemic signs could be at increased risk of haemorrhage after alteplase treatment, and little information is available about whether pre-existing structural signs, which are common in older patients, affect response to alteplase. We aimed to investigate the association between imaging signs on brain CT and outcomes after alteplase.

Methods IST-3 was a multicentre, randomised controlled trial of intravenous alteplase (0.9 mg/kg) versus control within 6 h of acute ischaemic stroke. The primary outcome was independence at 6 months (defined as an Oxford Handicap Scale [OHS] score of 0-2). 3035 patients were enrolled to IST-3 and underwent pre-randomisation brain CT. Experts who were unaware of the random allocation assessed scans for early signs of ischaemia (tissue hypodensity, infarct extent, swelling, and hyperattenuated artery) and pre-existing signs (old infarct, leukoaraiosis, and atrophy). In this prespecified analysis, we assessed interactions between these imaging signs, symptomatic intracranial haemorrhage (a secondary outcome in IST-3) and independence at 6 months, and alteplase, adjusting for baseline number of Health Stroke Scale (NIHSS) score, and time to randomisation. This trial is registered with ISRCTN25765518.

Findings 3017 patients were assessed in this analysis, of whom 1508 received alteplase. Onset to treatment time, NIHSS [DRAGON], Total Tissue-based control. A reduction in independence was predicted by older age, larger stroke volume, and larger stroke volume. The benefit of alteplase was reduced in patients with larger stroke volume and older age. The benefit of alteplase was reduced in patients with larger stroke volume and older age. The benefit of alteplase was reduced in patients with larger stroke volume and older age.

Conclusions—There is a clinically relevant net positive effect of r-tPA in patients with acute ischaemic stroke who have early ischaemic signs on brain CT and outcomes after alteplase.

Targeting Receptor-1 Activator in Acute Intracranial Hemorrhage: An Analysis of the IST-3 Collaborative Group

William N. Whiteley, Geoff Cohen, MA; Richard I. Lindley, MD; Peter Sandercock, MD

Background and Purpose—Intravenous symptomatic intracranial hemorrhage (sICH) models could identify patients least likely to benefit from alteplase.

Methods—We used the Third International Stroke Trial (IST-3) randomised trial of 0.9 mg/kg r-tPA to develop a new model using variables of death or dependency with r-tPA in patients with acute ischaemic stroke.

Results—Prediction models for sICH or poor functional outcome were developed using variables of death or dependency with r-tPA in patients with acute ischaemic stroke.

Conclusions—There is a clinically relevant net positive effect of r-tPA in patients with acute ischaemic stroke who have early ischaemic signs on brain CT and outcomes after alteplase.

Activator for acute intracranial hemorrhage and meta-analysis

Abstract

Background: Intravenous recombinant tissue plasminogen activator (rtPA) is approved for use in patients with acute ischaemic stroke who meet strictly defined criteria. IST-3 sought to test the validity and precision of the estimates of the overall treatment effects (efficacy and safety) of intravenous recombinant tissue plasminogen activator (rtPA) in acute ischaemic stroke, and to determine whether a wider range of patients (including those with developing symptoms, and brain imaging evidence of acute ischaemic stroke) would benefit from treatment. **Design:** International, multicentre, prospective, randomised controlled trial. **Results:** The initial pilot phase was completed in 2007. Recruitment began on 05/05/2009. Only 61.2% (296) of whom
